14. Tableau Story and Narrative

Narrative arc

The story should move from dataset context to composition, then technical and commercial comparisons, and finally limitations.

Story point 1 — What does the dataset contain?

The supplied file contains 100,000 records and 37 fields across 15 categories, 200 manufacturers, and 7 market regions. Make clear that these are counts of rows/labels in the file, not a verified census of the EV industry.

Story point 2 — How is the dataset composed?

`Two-Wheeler Scooter` is the most frequent category with 9,826 records (9.83%). Show a sorted category bar chart and call attention to unequal category counts.

Story point 3 — How do recorded prices vary?

Mean price is $65,010.46, while median price is $42,808.69. The difference suggests a right-skewed distribution; a box plot and category medians are more informative than a mean-only comparison.

Story point 4 — What range and battery patterns appear?

Mean range is 324.3 km and median range is 338.3 km. Battery capacity and range are positively correlated (r = 0.266), but the association is modest and does not establish a causal relationship.

Story point 5 — Which relationships need caution?

Price and battery capacity have r = 0.837. Annual sales have a high maximum and are missing for 989 records, so medians, distributions, and outlier review should accompany any average.

Story point 6 — What are the limitations?

The file has 9,511 missing cells and no supplied source methodology. The meanings of annual sales, CO■ saved, and ratings need verification. Conclude with a concise, evidence-based summary and disclose these limitations.

Presentation rule

The story must match the final published Tableau workbook. If the visualized values differ because filters or cleaning were applied, update the figures and explain the difference rather than copying the raw-file numbers unchanged.
